

Do Foreign Capital Inflows Boost Domestic Savings in Pakistan? A Time Series Analysis

Muhammad Ramzan Sheikh¹, Maria Batool² and Irfan Hussain³

<https://doi.org/10.62345/jads.2021.10.2.2>

Abstract

This paper investigates the impact of foreign capital inflows on domestic savings in Pakistan. The annual time series data has been used from the period 1972 to 2018 by applying ARDL and causality analysis. The results show that labor force participation rate, gross fixed capital formation, deposit interest rate, foreign direct investment, trade, GDP growth and foreign remittances have a positive impact on gross domestic savings in the long run but the variables of age dependency, external debt stock and net official development assistance have a negative impact on gross domestic savings. The coefficient of error correction model shows that the model is highly significant and converges towards equilibrium. The results of the Granger causality test exhibit that there is no causality between FDI, remittances, TRADE, external debt and gross domestic savings except ODA and GDS which shows the unilateral causality.

Keywords: Foreign Aid, FDI, Foreign Debt, Remittances, ARDL, Causality Analysis.

1. Introduction

The nature has endowed Pakistan a lot of human and natural resources including mountains, deserts, irrigated lands and four seasons so Pakistan can be a suitable country for domestic and foreign investors. Government of Pakistan knows the requirements of foreign investors therefore a comprehensive and investment friendly policies are being devised. Savings are very vital for capital formation, productivity and sustainable development. Foreign capital inflows have a significant role in the growth process of the capital-deficient productive capacity of the economy. Foreign capital inflows are the main resources that enhance domestic savings as well as the economic growth of a nation from the developing world. These have also been considered the key element in the process of economic globalization and integration. Foreign capital inflows boost up the economic development in a country and increase the production and job opportunities in an economy (Ahmad et al., 2002).

Foreign capital inflows play a very important role in low-income countries because there is a lack of modern technology, capital and skilled labor (Ahmad, 1986). The major components of foreign capital inflows are foreign direct investment, foreign aid, foreign remittances and foreign debt. Domestic savings plays an essential role in the economic growth progress in an

economy. It can help the economy to become financially strong (Chaudhry et al., 2009). Domestic savings are important in emergency case. It can also be used in many ways for example to build a factory, to start a new business, to invest in the existing business, to enhance a business, etc. There are a lot of studies that have done to explain the link between foreign capital inflows (FCI) and domestic savings. This study shows the link between foreign capital inflows and domestic savings in Pakistan from the period 1972 to 2018 by using time series data.

The plan of the paper is as follows: Section 2 presents the review of the literature. Model specification is given in section 3. Section 4 describes data and ARDL model specification. Section 5 explains the results and discussions. Section 6 consists of the conclusion and policy recommendations.

2. Foreign Capital Inflows and Savings: An Empirical Review

In this section, we are reviewing the studies that are based on foreign capital inflows and savings. Hamdar and Nouayhid (2017) examined the role of foreign capital inflows on savings and investment in a less developed country. The authors used the time series data from the period 1989 to 2010 by applying OLS. The researchers used savings as a dependent variable while the variables of investment and foreign capital inflows were used as independent variables. The study found a negative association of capital inflows, domestic savings and investment because the amount of profit that is earned through foreign capital inflows is used to build and maintain infrastructure like schools, roads etc. in less developed countries like Lebanon.

Hossain (2014) analyzed the impact of foreign capital inflows on domestic savings in developing countries. The researcher used the panel data from the period 1971 to 2010 and applied the common correlated effects mean group (CCEMG) technique. The study found a negative relationship between foreign capital inflows and domestic savings because FCI was used to enhance foreign reserves and to decrease the deficits that exist in the balance of payment in developing nations.

Ali and Nishat (2009) discussed the impact of foreign capital inflows on domestic savings in developing countries. The researchers used the time series data from the period 1975 to 2008. The study used the OLS and ARDL methodology. The researchers used foreign capital inflows as explanatory variables while domestic savings as a dependent variable. The authors found a negative relationship between foreign capital inflows and domestic savings in developing countries because the link between the employment rate and foreign capital inflows is positive that's why foreign capital inflows become the cause to raise the employment rate. As we know Pakistan is a consumption-oriented country so the main part of the income of the people is used for consumption purposes which becomes the cause of the low savings rate.

Verma and Wilson (2005) highlighted the association between FCI, economic growth, investment and domestic savings in a developing country. The study used time-series data from the period 1950 to 2001 and utilized the full information maximum likelihood method and cointegration technique. The authors used foreign capital inflows and economic growth as independent variables and domestic savings and investment as dependent variables. The researchers found a negative relationship between foreign capital inflows and domestic savings.

Ahmad et al. (2002) examined the impact of foreign capital inflows on domestic savings in Pakistan from the period 1972 to 2000. The results were estimated by applying the error correction model and cointegration techniques. The authors found a negative relationship between foreign capital inflows and domestic savings because the foreign capital inflows are used to make the resources that are not so beneficial for the people in developing countries and the revenues which were generated by using these resources increased the consumption and became an obstacle to enhance domestic savings in Pakistan.

Khan et al. (1992) estimated the impact of foreign capital inflows on domestic savings in a low-income country. The study used the time series data from the period 1959 to 1988 and applied the OLS method. The authors found the negative linkage of foreign capital inflows with domestic savings because the maximum amount of foreign capital inflows were used for consumption purposes which were considered as the main hurdle to accelerate domestic savings in Pakistan.

Mapalad (1998) investigated the link between foreign capital inflows and domestic savings in the Philippines. The study was based on time-series data from the period 1952 to 1993. The researcher found no direct link between foreign capital inflows and domestic savings by applying two stages least squares technique and inferred that national savings rate was mainly determined by these variables: its lagged value, augmentation of per capita real income and balance of payment crises as induced by a model in the less developed country.

Aslam (1987) pointed out the connection between foreign capital inflows and domestic savings and investment in Pakistan from the period 1963 to 1985. The results of the study were estimated through the multiple regression analysis technique. The study found the negative association of inflows of capital with domestic savings because dependency on foreign capital inflows forced the country to have low growth which decreased the real wage rate and became the cause of low savings in Pakistan.

Ahmad (1986) highlighted the impact of foreign capital inflows on domestic savings in Bangladesh from the period 1960 to 1980. The estimation technique which was used in this study was the two stages least square method. The author found a non-negative association between domestic savings and foreign capital inflows because foreign capital inflows did not replace domestic savings in Bangladesh.

Chen (1977) asserted the effect of foreign capital inflows on domestic savings in the developing countries from the period 1956 to 1971. The methods which were used for the estimation were the OLS method and two stages least squares technique. The study found a negative relationship between foreign capital inflows and domestic savings due to official inflows. The relationship between these variables (foreign capital inflows and domestic savings) varied from nation to nation. In certain nations, it was positive and in others it was negative.

Grinols and Bhagwati (1976) probed the link between foreign capital inflows and domestic savings in less developed countries from the period 1960 to 1970. The study found a negative association between foreign capital inflows and domestic savings because developing countries depended on foreign loans and the number of foreign capital inflows was used for the repayment of the loan and its interest. Due to this, the number of foreign capital inflows might not be used for the investment which indicated low domestic saving in developing nations.

From the above-mentioned studies, we have concluded that all the studies have the same view about the negative relationship between foreign capital inflows and savings. The studies

were mostly on developing countries and the authors have used two stages least squares (2SLS) method, ordinary least square (OLS) method, generalized method of moment (GMM) technique, autoregressive distributed lag (ARDL) model, error correction model (ECM) and cointegration techniques. The studies give various reasons for the negative link between foreign capital inflows and saving: foreign capital inflows do not replace domestic savings.

3. Model Specification

To examine the linkage between foreign capital inflows and gross domestic savings in Pakistan, the following model is displayed in equation (1).

$$GDS = f(LFPR, GFCF, GDPG, DR, DEPR, FDI, REM, TRADE, ED, ODA) \quad (1)$$

In this model, the dependent variable is gross domestic savings (GDS) and independent variables are labor force participation rate, gross fixed capital formation, GDP growth, deposit interest rate, age dependency ratio, foreign direct investment, remittances, trade, external debt stock and net ODA.

The econometric form is shown in equation (2):

$$GDS = \beta_0 + \beta_1 LFPR + \beta_2 GFCF + \beta_3 GDPG + \beta_4 DR + \beta_5 DEPR + \beta_6 FDI + \beta_7 REM + \beta_8 TRADE + \beta_9 ED + \beta_{10} ODA + \mu \quad (2)$$

Where:

GDS = Gross Domestic Savings (% of GDP)

LFPR = Labor force participation rate (% of total population ages 15+)

GFCF = Gross fixed capital formation (% of GDP)

GDPG = GDP growth (annual %)

DR = Deposit interest rate (%)

DEPR = Age dependency ratio (% of working-age population)

FDI = Foreign direct investment, net inflows (% of GDP)

REM = Personal remittances received (% of GDP)

TRADE = Trade (% of GDP)

ED = External debt stocks (% of GDP)

ODA = Official development assistance (% of GNI)

4. Data and Methodology

The data used is annual time series data of Pakistan ranging from 1972 to 2018. Data used in the analysis are taken from World Development Indicators. We have applied the ARDL technique to estimate the results. The general form of ECM (error correction model) is given in equation (3) which explain the impact of foreign capital inflows (foreign aid, foreign direct investment, foreign debt, foreign remittances, trade, gross domestic product growth, gross fixed capital formation, age dependency ratio, deposit interest rate and labor force participation rate) on gross domestic savings.

$$\begin{aligned}
\Delta(GDS)_t = & \alpha + \beta_1(GDS)_{t-1} + \beta_2(LFPR)_{t-1} + \beta_3(GFCF)_{t-1} + \beta_4(GDPG)_{t-1} + \beta_5(DR)_{t-1} \\
& + \beta_6(DEPR)_{t-1} + \beta_7(FDI)_{t-1} + \beta_8(REM)_{t-1} + \beta_9(TRADE)_{t-1} + \beta_{10}(ED)_{t-1} \\
& + \beta_{11}(ODA)_{t-1} + \sum_{i=1}^{a_1} \delta_1 \Delta(GDS)_{t-i} + \sum_{i=0}^{a_2} \delta_2 \Delta(LFPR)_{t-i} + \sum_{i=0}^{a_3} \delta_3 \Delta(GFCF)_{t-i} \\
& + \sum_{i=0}^{a_4} \delta_4 \Delta(GDPG)_{t-i} + \sum_{i=0}^{a_5} \delta_5 \Delta(DR)_{t-i} + \sum_{i=0}^{a_6} \delta_6 \Delta(DEPR)_{t-i} + \sum_{i=0}^{a_7} \delta_7 \Delta(FDI)_{t-i} \\
& + \sum_{i=0}^{a_8} \delta_8 \Delta(REM)_{t-i} + \sum_{i=0}^{a_9} \delta_9 \Delta(TRADE)_{t-i} + \sum_{i=0}^{a_{10}} \delta_{10} \Delta(ED)_{t-i} + \sum_{i=0}^{a_{11}} \delta_{11} \Delta(ODA)_{t-i} + \varepsilon_t
\end{aligned} \tag{3}$$

The coefficient of long-run parameters are β_i and in the autoregressive distributed lag model (ARDL) the short-run dynamic coefficients are δ_i . The error term is ε_t while Δ is the operator of the first difference. If a long-run relationship exists, long-run coefficients are estimated through the following equation (4).

$$\begin{aligned}
\Delta(GDS)_t = & \alpha + \sum_{i=1}^{a_1} \eta_1(GDS)_{t-i} + \sum_{i=0}^{a_2} \eta_2(LFPR)_{t-i} + \sum_{i=0}^{a_3} \eta_3(GFCF)_{t-i} + \sum_{i=0}^{a_4} \eta_4(GDPG)_{t-i} \\
& + \sum_{i=0}^{a_5} \eta_5(DR)_{t-i} + \sum_{i=0}^{a_6} \eta_6(DEPR)_{t-i} + \sum_{i=0}^{a_7} \eta_7(FDI)_{t-i} + \sum_{i=0}^{a_8} \eta_8(REM)_{t-i} \\
& + \sum_{i=0}^{a_9} \eta_9(TRADE)_{t-i} + \sum_{i=0}^{a_{10}} \eta_{10}(ED)_{t-i} + \sum_{i=0}^{a_{11}} \eta_{11}(ODA)_{t-i} + \varepsilon_t
\end{aligned} \tag{4}$$

The short-run domestic savings equation in ARDL model can be estimated with equation (5).

$$\begin{aligned}
\Delta(GDS)_t = & \alpha + \sum_{i=1}^{a_1} \lambda_1 \Delta(GDS)_{t-i} + \sum_{i=0}^{a_2} \lambda_2 \Delta(LFPR)_{t-i} + \sum_{i=0}^{a_3} \lambda_3 \Delta(GFCF)_{t-i} + \sum_{i=0}^{a_4} \lambda_4 \Delta(GDPG)_{t-i} \\
& + \sum_{i=0}^{a_5} \lambda_5 \Delta(DR)_{t-i} + \sum_{i=0}^{a_6} \lambda_6 \Delta(DEPR)_{t-i} + \sum_{i=0}^{a_7} \lambda_7 \Delta(FDI)_{t-i} + \sum_{i=0}^{a_8} \lambda_8 \Delta(REM)_{t-i} \\
& + \sum_{i=0}^{a_9} \lambda_9 \Delta(TRADE)_{t-i} + \sum_{i=0}^{a_{10}} \lambda_{10} \Delta(ED)_{t-i} + \sum_{i=0}^{a_{11}} \lambda_{11} \Delta(ODA)_{t-i} + \omega ECM_{t-1} + \varepsilon_t
\end{aligned} \tag{5}$$

The parameters with summation signs denote the short-run coefficients and parameters of the error correction model (ECM). ω represent the speed of adjustment.

5. Results and Discussions

5.1 Descriptive Statistics and Correlation Analysis

Table 1 shows the results of descriptive statistics of the main variables with respect to 1972 to 2018.

Table 1: Descriptive Statistics of Key Variables (1972-2018)

	Mean	Median	Max	Min	SD	Skewness	Kurtosis	JB	Prob.	Obs.
GDS	10.67	10.06	17.61	1.45	4.35	0.04	2.03	1.81	0.40	46
LFPR	30.19	29.82	32.98	27.46	1.68	0.32	1.96	2.83	0.24	46
GFCF	15.81	16.49	19.24	11.44	2.10	-0.67	2.32	4.33	0.11	46
GDPG	4.82	4.84	10.22	0.81	2.10	0.20	2.67	0.52	0.77	46
DR	6.39	7.19	10.17	-1.63	2.23	-1.60	5.90	35.89	0.00	46
DEPR	81.44	86.98	88.91	65.08	8.53	-0.77	1.87	6.94	0.03	46
FDI	0.68	0.50	3.67	-1.18	0.91	1.44	6.03	33.42	0.00	46
REM	5.13	4.96	10.25	1.45	2.17	0.23	2.22	1.55	0.46	46
TRADE	33.53	33.35	38.91	27.72	2.75	-0.18	2.69	0.43	0.81	46
ED	0.26	0.26	0.35	0.19	0.04	0.24	1.97	2.48	0.29	46
ODA	2.43	2.11	7.48	0.71	1.46	1.51	5.49	29.29	0.00	46

DEPR has the highest mean value which is 81.44 % of the working age population and ED has the lowest mean value which is 0.26 % of GDP in the set of data. DEPR has the highest median value in the arranged set of data which is 86.98 % of the working-age population and ED has the lowest mid-value which is 0.26 % of GDP. Max represents the maximum values in the series. Min shows the minimum values in the whole set of data. DEPR has the maximum value in the whole set of data which is 88.91 % of the working-age population. DR has the minimum value in the series which is -1.63 %. DEPR has the highest value of standard deviation in the whole set of data and that is 8.53 % of the working-age population which shows the greater spread in the series and ED has the lowest value of standard deviation in the whole series which shows the distance of individual value from the average or mean value that is round about 0.04 % of GDP. The variables GDS, LFPR, GDPG, FDI, REM, ED and ODA are positively skewed. While the other variables GFCF, DR, DEPR and TRADE are negatively skewed. The variables DR, FDI and ODA are leptokurtic. All the other variables GDS, GFCF, GDPG, LFPR, DEPR, ED, REM and TRADE are platykurtic. The probability value of JB stats of GDS, LFPR, GFCF, GDPG, REM, TRADE and ED of these variables are in a symmetrical distribution. The other variables DR, DEPR, FDI and ODA are in non-symmetrical distribution exploring the data with respect to 1972 to 2018 in Pakistan.

Table 2 shows the results of the correlation matrix of the main variables. There is a negative moderate correlation between GDS and LFPR because its value is -0.55. GDS has a positive moderate correlation with GFCF and FDI. GDS has a negative weak correlation with GDPG and ODA. There is a positive weak correlation between the variables GDS and TRADE, GDS and ED and GDS and DEPR. GDS has a negative strong correlation with REM. LFPR has a negative moderate correlation with GFCF and TRADE. LFPR has a negative weak correlation with GDPG, DR and ODA. LFPR has a negative strong correlation with DEPR because its value is -0.82. LFPR has a positive moderate correlation with ED and REM. LFPR has a positive weak correlation with FDI.

Table 2: Correlation Matrix of Key Variables (1972-2018)

Correlation	GDS	LFPR	GFCF	GDPG	DR	DEPR	FDI	REM	TRADE	ED	ODA
GDS	1.00										
LFPR	-0.55	1.00									
GFCF	0.40	-0.45	1.00								
GDPG	-0.13	-0.09	0.23	1.00							
DR	-0.33	-0.03	0.26	-0.05	1.00						
DEPR	0.20	-0.82	0.50	0.23	0.23	1.00					
FDI	0.46	0.11	0.42	-0.15	-0.16	-0.23	1.00				
REM	-0.74	0.37	-0.14	0.44	0.18	-0.05	-0.44	1.00			
TRADE	0.14	-0.31	0.40	0.08	0.37	0.16	0.26	-0.07	1.00		
ED	0.04	0.43	-0.30	-0.13	-0.20	-0.78	0.13	-0.08	0.12	1.00	
ODA	-0.21	-0.27	0.12	0.18	0.10	0.60	-0.31	0.10	-0.16	-0.75	1.00

GFCF has a positive weak correlation with GDPG, DR and ODA. GFCF has a positive moderate correlation with DEPR, FDI and TRADE. GFCF has a negative weak correlation with REM. GFCF has a negative moderate correlation with ED. There is a negative weak correlation between GDPG and DR, GDPG and FDI and GDPG and ED. GDPG has a positive weak correlation with DEPR, TRADE and ODA. DR has a positive weak correlation with DEPR, REM and ODA. DR has a positive moderate correlation with TRADE because the coefficient value of TRADE is 0.37. DEPR has a negative weak correlation with FDI and REM. DEPR has a positive weak correlation with TRADE. DEPR has a negative strong correlation with ED. DEPR has a positive moderate correlation with ODA. FDI has a negative moderate correlation with REM and ODA. FDI has a positive weak correlation with TRADE and ED because the coefficient value of these variables are 0.26 and 0.13 which represent the weak correlation and sign of the coefficient are positive that's why it shows the positive weak correlation between these variables. There is a negative weak correlation between REM and TRADE and REM and ED because the coefficient values of these variables are -0.07 and -0.08. There is a positive weak correlation between REM and ODA. There is a positive weak correlation between TRADE and ED. TRADE and ODA has a negative weak correlation because the sign of the coefficient is negative that is why there is a negative weak correlation between TRADE and ODA. ED and ODA have a negative strong correlation during the period from 1972 to 2018.

5.2 Results of ADF Unit Root

Table 3 shows the results of ADF unit root analysis. The results of the ADF test show that there is mixed order of integration among the variables. So, the optimum methodology suggested by the econometricians is ARDL so, we would apply ARDL for the estimation of the model.

Table 3: ADF Unit Root Test Results

Unit Root Test on Level							
Variables	Intercept	Lags	Intercept & Trend	Lags	None	Lags	Conclusion
GDS	-2.06 (0.25)	0	-2.04 (0.56)	0	-0.60 (0.44)	0	NS
LFPR	-0.84 (0.79)	0	-1.31 (0.87)	0	0.50 (0.82)	0	NS
GFCF	-2.23 (0.19)	0	-2.71 (0.23)	0	-0.01 (0.67)	0	NS
GDPG	-5.13 (0.00)	0	-5.78 (0.00)	0	-1.49 (0.12)	0	S
DR	-2.01 (0.27)	0	-2.19 (0.48)	0	-0.63 (0.43)	0	NS
DEPR	-2.60 (0.09)	3	-2.69 (0.24)	3	-2.52 (0.01)	0	S
FDI	-2.80 (0.06)	1	-2.87 (0.17)	1	-1.52 (0.11)	0	S
REM	-1.93 (0.31)	0	-2.57 (0.54)	0	-0.64 (0.42)	0	NS
TRADE	-3.56 (0.01)	0	-3.49 (0.05)	0	-0.09 (0.70)	0	S
ED	-1.74 (0.40)	0	-4.62 (0.00)	0	-0.51 (0.82)	0	NS
ODA	-2.09 (0.24)	0	-4.04 (0.01)	0	-1.70 (0.08)	0	S

5.3 Results of Bounds Test

Table 4 shows the results of the bounds test analysis. It shows that the value of the F-statistic is greater than the upper bound I (1) at 5% and 10% level of significance.

Table 4: Bounds Test based on F-Test

		5% Critical Value Bounds		10% Critical value Bounds	
Model	F-Statistic	I(0)	I(1)	I(0)	I(1)
GDS/ LFPR GFCF GDPG DR DEPR FDI REM TRADE ED ODA	3.898275	2.06	3.24	1.83	2.94

That is why the long-run relationship exists and when a long-run relationship exists it means cointegration also exist.

5.4 Long Run Results

Now we explain the long run results which are shown in Table 5. There is a positive and significant relationship between GDS and LFPR in the long run. As labor force participation increase, it will enhance the production of industrial units. It will enable the industry to do efficient production. Efficient and more production in industrial units will attract the people for more investment in different industries. For more investment, people will borrow from the banking sector. More demand for loans can be fulfilled by urging people to enhance their savings. Secondly, more investment will lead to more production. More productivity means more GDP growth that will become the cause of an increase in gross domestic savings (Graham, 1987; Oropesa, Yamada et al., 1990 and Joubert and Todd, 2011).

In an economy for efficiency and more production, there is a need to replace the old capital goods with new capital assets. This is also essential to increase the capital goods like machinery, labor, tools and transportation assets to increase the productivity of different sectors in the economy. This process is called capital formulation. It would be beneficial only when there is the best and efficient utilization of these resources. The capital goods can be attained domestically as well as through foreign investments. If there is more capital formulation in different sectors, there will be more production units that will have efficient production of goods and services. This will positively influence the gross domestic product and become the cause of high GDP growth. More growth in the gross domestic product will uplift the domestic savings of the country. So, the coefficient value of GFCF is 1.57. The coefficient is positive which represent the positive and significant relationship between GDS and GFCF in long run. Our results are compatible with the studies (Kanu et al., 2014; Jagadeesh, 2015; Shuaib et al, 2015; Gibescu, 2010; and Armstrong et al, 1996).

Table 5: Long Run Estimates of Foreign Capital Inflows and Domestic Savings

Dependent Variable: GDS				
Selected Model: ARDL(1, 1, 2, 2, 0, 0, 1, 0, 1, 2, 0)				
Variable	Coefficient	Std. Error	t-Stat	Prob.
LFPR	1.331079	0.601742	2.212043	0.0372
GFCF	1.577382	0.396808	3.975176	0.0006
GDPG	0.696735	0.419356	1.661441	0.1102
DR	0.717473	0.219922	3.262401	0.0034
DEPR	-0.471273	0.170875	-2.757992	0.0112
FDI	1.593886	0.758833	2.100445	0.0469
REM	0.886175	0.304680	2.908544	0.0079
TRADE	0.346237	0.209057	1.656187	0.1113
ED	-0.798129	0.251496	-3.173530	0.0042
ODA	-1.036126	0.424761	-2.439315	0.0228
C	89.394122	35.363465	2.527867	0.0188

It is obvious that if there is high GDP growth in the economy, it will lead to more gross domestic savings. Different methods can help to increase the GDP growth i.e. if the banks charge a low policy rate, people will get more loans that will prove beneficial to increase the economic activity as well as GDP growth. In this modern era, the best way to uplift GDP growth is to do innovation in all sectors. This will decrease the cost of doing business as well

as enhance productivity which ultimately increases the GDP growth and domestic savings. The sign of the coefficient of GDPG is positive which shows the long-run positive and insignificant relationship between GDPG and GDS. The studies by Waithima, 2008; Odhiambo, 2009; Oladipo, 2010 and Misztal, 2011 have found the positive impact of GDS on GDP growth.

If the central bank of the country increases the deposit rate, it will attract the people for more savings in banks. Through more savings, the supply of loanable funds will increase in banks. When the supply of loanable funds increases, it will push down the policy rate which bank advance the loans to the people. The investor will demand more loans from banks to put these in economic activities at a low-interest rate. The investors borrow the loan from banks and invest it into economic activity and that will enhance the production of different sectors. It will also increase the profitability ratio of investors which attracts the other investors from their home country or abroad to put their investment in these sectors. Through more profit, the investors can reallocate their savings in different economic units. These all steps positively influence the gross domestic product as well as gross domestic savings. The coefficient value of DR is 0.71, which shows the positive and significant relationship between DR and GDS in the long run. So, our results are in line with the studies (Mushtaq and Siddiqui 2017; Oshikoya, 1992 and Molho, 1986).

In an economy, when the burden of old-age people increases, domestic savings will go down. The reason behind this negative relation is that people who are retired from their jobs and use their saved part of the money. They are not participating in economic activity but they are using their saved resources to meet their basic needs. These people are considered as a burden on the economy because they are using the saved part of money without earnings. When in an economy people of this category increases, there will be less domestic savings. So, the negative sign of DEPR shows the negative and significant relationship between DEPR and GDS in the long run. Our results are consistent with the studies (Apergis and Christou, 2012; Keho, 2012 and Gupta, 1975).

The economic reason for the positive relationship between foreign direct investment and domestic savings is that more foreign direct investment will generate more economic activity. Gross domestic product will increase due to foreign direct investment and it will enhance domestic savings. FDI is also used in productive ways that will lead to high economic growth and an increase in domestic savings. FDI enhances the investment in a country creating more economic growth and domestic savings. The estimated parameter of FDI is positive and statistically significant. So, our results are supported by different studies which are Bano and Tabbada (2015); Hassen and Anis (2012); Chani et al, (2010) and Dhar and Roy (1996).

If the residents of the country send more remittances back towards their country, this money may be used for consumption and savings purposes. More consumption leads to an increase in aggregate demand of an economy and that will increase the economic activity as well as GDP and domestic savings. Another use of remittances is to save money. The majority of people save their money in banks and this amount can be used as loanable funds. This activity generates the investment in economy which will improve economic growth and increase domestic savings because foreign remittances contribute to encourage financial development and help to eliminate poverty conditions. In this way, remittance inflows play a vital role in promoting economic activity and lead to a decrease in poverty alleviation in developing countries. The coefficient represents the long-run positive and significant relationship

between REM and GDS. Our results are compatible with the studies (Inoue, 2018; Azam et al, 2016; Imai et al, 2014; Lartey, 2013; Javid et al, 2012; Baldé, 2011 and Morton et al, 2010).

A good relationship between countries has a positive impact on trade. If more trade-in economy, it means that there is a high GDP growth rate that will lead to more domestic savings. The coefficient of TRADE is 0.34 which shows the positive and insignificant relationship between TRADE and GDS in the long run. So, our results are consistent with the studies (Inoue, 2018; Lartey, 2013 and Gruben and Mcleod, 1998, Sheikh et al. 2018; Sheikh et al. 2019).

If a country is facing an external debt burden, then the major part of the gross domestic product of the economy is used for debt services that will negatively impact gross domestic savings. Debt burden hangover economies and scares off investors due to high anticipated future tax reduces public savings. The inverse linkage between debt burden and domestic savings is that foreign funds appear to substitute domestic savings and the resources generated through foreign debt have been used partially for spending purposes. So, the estimated value of ED also shows that there is a negative and statistically significant relationship between ED and GDS. The studies by Sheikh et al. 2015; Oageng and Boitumelo, 2017; Jappelli et al., 2014; Aliyu and Usman, 2013; Chaudhry et al, 2009 and Okafor and Tyrowicz, 2009 have found the negative impact of ED on GDS.

Net official development assistance has a negative impact on economic growth because the countries are dependent and the miscellaneous course of actions and self-governing expansion for the reason that democracies are the major problems to imperfections. Foreign aid is used for the development projects in the low-income countries because the poor countries magnetize the largest part of aid infraction to their earnings and the poor countries hoard least not the actual in the less developed countries and developing countries are dependent on developed countries. Corruption and political instability are also the main reasons for this correlation. So, the coefficient shows the negative and insignificant relationship between ODA and GDS in the long run. Our results are compatible with the studies (Afawubo and Mathey, 2017; Mohey-ud-din, 2005; Bowles, 1987 and Mosley, 1980).

6.5 Error Correction Results

The results of error correction estimates are being discussed in Table 6. The results show that the coefficient of error correction term is negative and the model is highly significant and converges towards the equilibrium.

Table 6: Error Correction Estimates of Foreign Capital Inflows and Domestic Savings

Dependent Variable: GDS				
Selected Model: ARDL(1, 1, 2, 2, 0, 0, 1, 0, 1, 2, 0)				
Variable	Coefficient	Std. Error	t-Stat	Prob.
D(LFPR)	0.112061	0.718251	0.156019	0.8774
D(GFCF)	1.017616	0.389417	2.613176	0.0155
D(GFCF(-1))	-0.765257	0.358479	-2.134730	0.0437
D(GDPG)	0.050045	0.167854	0.298146	0.7683
D(GDPG(-1))	0.269141	0.205715	1.308323	0.2037
D(DR)	-0.692286	0.204963	-3.377611	0.0026
D(DEPR)	-0.454729	0.185964	-2.445250	0.0225

D(FDI)	0.231846	0.714896	0.324308	0.7486
D(REM)	-0.855065	0.362697	-2.357522	0.0273
D(TRADE)	0.040320	0.166487	0.242178	0.8108
D(ED)	-0.568675	0.179807	-3.162696	0.0043
D(ED(-1))	0.440809	0.170434	2.586386	0.0165
D(ODA)	-0.999752	0.471164	-2.121879	0.0448
CointEq(-1)	-0.964894	0.176519	-5.466246	0.0000

The coefficient of error correction term communicates that it takes 9 months or roundabout 1 year to be correct.

6.5 Granger Causality Analysis

Granger causality test is used to check the causality between two variables mostly in time series analysis. The first step in the analysis of Granger causality is to choose optimum lag. Table 7 shows the lag selection criteria. According to the results, the optimum lag is 2 because at lag 2 the value of AIC and SC has the minimum values.

Table 7: VAR Lag Order Selection Criteria

Endogenous variables: GDS LFPR GFCF GDPG DR DEPR FDI REM TRADE ED ODA						
Lag	Log L	LR	FPE	AIC	SC	HQ
0	-717.6621	NA	6.715680	33.12101	33.56705	33.28642
1	-396.1230	467.6934	0.000863	24.00559	29.35816*	25.99058
2	-216.4936	171.4644*	0.000182*	21.34062*	31.59971	25.14518*

Table 8 shows the result of the Granger causality test. At first, we take GDS (gross domestic savings) dependent variable and independent variables are LFPR, GFCF, GDPG (GDP growth), DR (deposit interest rate), DEPR (age dependency ratio), FDI (foreign direct investment), REM (personal remittances), ED (external debt stock) and ODA (net ODA received). There is unilateral causality between the variables LFPR and GDS because LFPR Granger causes GDS but GDS does not Granger causes LFPR. There is no causality between GFCF and GDS because both variables do not Granger cause. There is also no causality exist between GDPG and GDS because GDPG does not Granger cause GDS at lag 2, 3 and 4 and GDS does not Granger cause GDPG at lag 2, 3 and 4. At lag 2, 3 and 4 DR does not Granger cause GDS and GDS does not Granger cause DR so, there is no causality exist between DR and GDS. Bilateral causality exists between DEPR and GDS because DEPR Granger causes GDS at lag 2, 3 and 4 and GDS Granger cause DEPR at lag 2 and 3 but does not cause at lag 4. So, we consider that GDS Granger causes DEPR because it causes two lags but does not cause one lag.

Table 8: Pairwise Granger Causality Test

FDI does not Granger cause GDS and GDS do not Granger cause FDI at lag 2, 3 and 4 so, there exist no causality between FDI and GDS. REM and GDS does not Granger cause at any of the given lags that is why there exists no causality between these variables. There is no causality between the variables TRADE and GDS because these variables do not Granger cause anymore at the given lags 2, 3 and 4. There exist no causality between ED and GDS because ED and GDS do not Granger cause at lag 2, 3 and 4. There is unilateral causality between ODA and GDS because ODA does not Granger cause GDS at lag 2, 3 and 4 but GDS Granger cause ODA at lag 2 and 3 so, there is one-way causality. LFPR has no causality with GFCF and GDPG. LFPR has unilateral causality with DR and DEPR there exist one-way causality between the variables. There exists no causality between FDI and LFPR because both variables do not Granger cause. REM and LFPR have unilateral causality because REM Granger causes LFPR at 2 and 4 lags but LFPR does not Granger cause REM in all the three lags. LFPR has no causality with TRADE, ED and ODA.

GDPG has unilateral causality with GFCF because GDPG Granger cause but GFCF does not. No causality exists between DR and GFCF the reason behind this is that both variables DR and GDPG do not Granger cause each other. There is one-way causality between DEPR and GFCF. GFCF has no causality with the variables FDI, REM, ODA and ED but unilateral causality with TRADE. GDPG has no causality with DR, DEPR, FDI, TRADE, ED and ODA because these variables do not Granger cause but GDPG has unilateral causality with REM the reason behind unilateral causality between GDPG and REM is that REM Granger cause GDPG at 2,3 and 4 lag and GDPG does not Granger cause REM at 2, 3 and 4 lags. DR has no causality with DEPR, REM, TRADE and ODA but unidirectional causality with FDI. There is unilateral causality between FDI and DEPR and bilateral or two-way causality between DEPR and REM. DEPR has no causality with TRADE, ED and ODA. FDI has no causality with REM, TRADE, ED and ODA. REM has one-way causality with TRADE and no causality with ED and ODA. TRADE has no causality with ED and ODA. And ED has no causality with ODA the reason behind this is that ODA does not Granger cause ED at any of the given lag and ED $\nRightarrow$ ODA at two, 3 and 4 lag. The sign $\nRightarrow$ represents that does not Granger Cause.

7. Conclusion and Policy Recommendations

In this study, we have discussed the impact of foreign capital inflows and domestic savings in Pakistan over the period 1972 to 2018. The empirical results of ARDL have concluded that gross domestic savings have a positive and significant impact on labor force participation rate, gross fixed capital formation, deposit interest rate, foreign direct investment and foreign

remittances but positive and insignificant relationship with trade and GDP growth. There is a negative and significant impact of age dependency ratio and external debt stock on gross domestic savings but net official development assistance has a negative and insignificant connection with gross domestic savings. The coefficient of error correction term shows that the model is highly significant and converges towards the equilibrium. The findings conclude that there is a positive linkage between foreign capital inflows and domestic savings in Pakistan. The results of the Granger causality test exhibit that there is no causality between FDI, remittances, TRADE, external debt and gross domestic savings except ODA and GDS which shows the unilateral causality.

Based on the findings of the study, the following policies may be devised:

- The government may focus on technical education. To enhance the industrial units this will enhance the LFPR.
- There is a need to focus on the government to provide opportunities for capital formation by creating ease of doing business.
- The central bank may increase the deposit interest rate so that more deposits would be possible in the savings account and gross domestic savings will increase.
- Policymakers may design policies that attract foreign direct investment from other countries which will have a positive impact on gross domestic product as well as gross domestic savings.
- The overseas may transfer their remittances to the country through a proper channel which can participate in the growth of GDP and have a positive impact on domestic savings.
